

Sure. During the testing, I performed a few basic Windows security/enumeration checks using built-in Windows commands to validate potential vulnerabilities on the IBML workstation. I did not execute or deploy any external tools, scripts, payloads, or exploitation frameworks. Shortly after running these checks, I received two security alerts and was disconnected from the workstation. I did not perform any further testing after the disconnection.

Regarding my current access, my workstation access is currently unavailable and my AD account has been disabled/locked. I also received the same account-lockout message when I attempted to communicate through Humana Teams. The Support team advised that they are unable to restore the access directly and that my manager needs to raise a ticket with the Access Management team.

I'm happy to provide the details of the commands/checks performed, along with any other information required to help with the investigation and deconfliction.
